PB-081

Clinical Validation of an Artificial-Intelligent (AI) Enabled Digital Test Using the Patient's Diagnostic Breast Biopsy to Predict Invasive Breast Cancer Recurrence within 6 years. Gerardo Fernandez, Jack Zeineh, Abishek Sainath Madduri, Richard Scott, Marcel Prastawa, Michael J. Donovan.

ckground

Invasive Breast cancer (IBC) has surpassed lung cancer as the leading diagnosed cancer worldwide, representing some 15.5% of all cancer

deaths. There remains an outstanding need to improve the current standard of care at diagnosis, including a reproducible and quantitative assessment of histologic grade and biological phenotype. We previously validated a digital laboratory-developed test to predict breast cancer recurrence using the surgical resection specimen. We now present the same approach for the diagnostic biopsy, providing a risk of recurrence earlier in the treatment planning and decision process.

Methods

1559 patients from 2004-2016 (Mount Sinai Health System, NY, NY, USA) with 6-year median follow-up divided 3:1, training (surgical cohort, 14% event rate) and validation (biopsy cohort, 13% event rate). H&E Whole slide Images (WSI), 40X magnification (Philips, Netherlands) were deconstructed with an Al-generated, precision medicine 'morphology feature array' (MFA) designed to extract tumor cell and tissue architectural features. Both cohorts were predominantly early-stage, ER/PR+ve, Her2-ve. Only age at diagnosis was utilized for biopsy model development. Recurrence events were classified as locoregional, distant metastasis and overall survival. C-index / AUC curves, Kaplan-Meier, hazards ratio, sensitivity, specificity, NPV, and PPV were used to assess risk discrimination.

Table 1. Demographics of the PreciseDx Breast Biopsy Train and Test Cohorts. Only ~44% of biopsy cases had ER/PR or HER2 status available. However, they are proportionately balanced with the training cohort.

Table 2. PreciseDx Breast Biopsy C-Index (CI) Train and Test models with Al-imaging features combined with age at diagnosis.

				CI	0.7605 (0 .72253, 0.80355)

Table 4. Utilization of the PreciseDx Breast Biopsy test (validation) model with cut-off to stratify patients into high and low recurrence risk groups.

Results

Surgical training model (n=1559), age (mean 60 years) (**Table 1**) combined with 7 imaging features representing an AI-(grade) yielded a C-index of 0.75 (95% Cl, 0.73-0.77) vs. clinical (age) 0.62 (95% Cl, 0.59-0.65) (**Table 2; Figure 1**). A risk score of 59.25 (scale 0-100) stratified patients as low- or high-risk, HR 4.9, P-value < 0.001, with sensitivity 0.71, specificity 0.71, NPV 0.94, and PPV 0.27 (Table 3, Figure 2) for predicting BC recurrence within six years. In the diagnostic biopsy validation cohort (n=570, Table 1), the model produced a C-index of 0.76 (95% CI, 0.72-0.80) vs. age only 0.65 (95%Cl, 0.59-0.71) (Table 2, Figure **3**). When patients were stratified by a risk score of 59.25, the HR was 4.9, P value <0.001), sensitivity 0.76, specificity 0.67, NPV 0.96, and PPV 0.22 for predicting BCR (Table 4, Figure 4). Examples of low and high-risk test patients are represented in Figures 5 and 6, respectively.

Figure 1. AUC - ROC curve of Training Model (n=1559, blue line) utilizing excision specimens and age at diagnosis: CI 0.75 (95% 0.73-0.77), HR4.9, p<0.001 vs. Clinical only model (orange line) using only age at diagnosis: CI 0.62 (95%CI 0.59-0.65), HR 2.27 p<0.001).

Figure 2. Kaplan-Meier of training model performance with a 59.25 cut-off distributing patients as high or low risk for breast cancer recurrence vs. age at diagnosis clinical model. HR= 4.9 (95%Cl, Cl,3.7-6.5, p<0.001).

				CI 95%	0.7536 (0.7292, 0.7751)

Table 3. PreciseDx Breast Biopsy training model with a cut-off to

Figure 6. Is an 82 y/o high risk woman(PreciseDx Breast Risk Score 74), clinically assigned Bloom-Richardson grade 2. Left panel shows the patient's H&E-stained biopsy with the mitotic figure detector overlay (yellow box with green box insert) and a higher magnification insert of detected mitotic figures. The right panel shows the same region of H&E-stained biopsy tissue and a gland morphology overlay with orange representing high grade gland morphology and blue representing low grade morphology.

Conclusion

We developed and validated a breast biopsy Al-enabled digital platform that successfully predicted early-stage BC recurrence within six years using only the H&E-stained image and age at diagnosis. The test is designed to assist in characterizing clinical risk and the overall management of patients at the time of diagnosis. Additional studies are underway to refine the impact on treatment selection further.

stratify patients into high and low-recurrence risk groups.

Figure 5 Is a 44 y/o low risk woman(PreciseDx Breast Risk Score 32), clinically assigned Bloom-Richardson grade 2. Left panel shows the patient's H&E-stained biopsy with the mitotic figure detector (none detected). The right panel shows the same region of H&E-stained biopsy tissue with a gland morphology overlay with orange representing high grade gland morphology and blue representing lower grade morphology.
